

MODEL PREDICTIVE CONTROL

STOCHASTIC MPC

Alberto Bemporad

imt.lu/ab

COURSE STRUCTURE

- ✓ Basic concepts of model predictive control (MPC) and linear MPC
- ✓ Linear time-varying and nonlinear MPC
- ✓ MPC computations: quadratic programming (QP), explicit MPC
- ✓ Hybrid MPC
 - Stochastic MPC
 - Data-driven MPC

Course page:

http://cse.lab.imtlucca.it/~bemporad/mpc_course.html

STOCHASTIC MODEL PREDICTIVE CONTROL

OPTIMIZE DECISIONS UNDER UNCERTAINTY

- In many control problems decisions must be taken under **uncertainty**

renewable power

prices

water

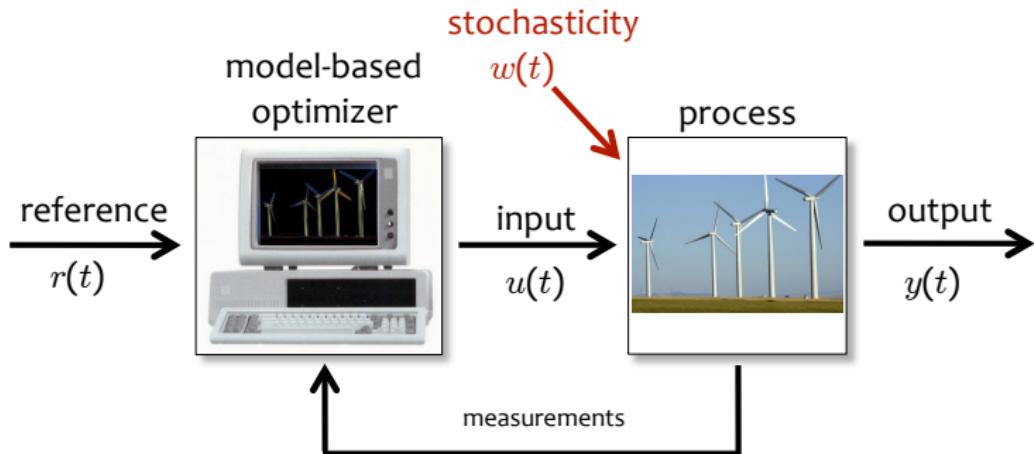

demand

human (inter)action

- Robust** control approaches do not model uncertainty (only assume that is bounded) and pessimistically consider the worst case
- Stochastic models** provide instead additional information about uncertainty
- Optimality** often sought (ex: minimize expected economic cost)

STOCHASTIC MODEL PREDICTIVE CONTROL (SMPC)

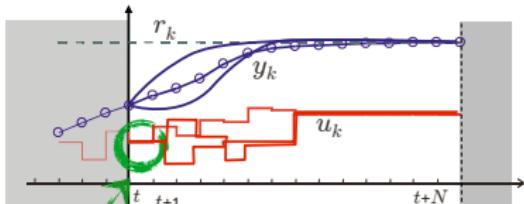

Use a **stochastic** dynamical **model** of the process to **predict** its possible future evolutions and choose the “best” **control** action

STOCHASTIC MODEL PREDICTIVE CONTROL

- At time t : solve a **stochastic optimal control** problem over a finite future horizon of N steps:

$$\begin{aligned} \min_u \quad & E_w \left[\sum_{k=0}^{N-1} \ell(y_k, u_k, w_k) \right] \\ \text{s.t.} \quad & x_{k+1} = A(w_k)x_k + B(w_k)u_k + f(w_k) \\ & y_k = C(w_k)x_k + D(w_k)u_k + g(w_k) \\ & u_{\min} \leq u_k \leq u_{\max} \\ & y_{\min} \leq y_k \leq y_{\max}, \forall w \quad \text{robustness} \\ & x_0 = x(t) \quad \text{feedback} \end{aligned}$$

- Solve stochastic optimal control problem w.r.t. future input sequence
- Apply the first optimal move $u(t) = u_0^*$, throw the rest of the sequence away
- At time $t+1$: Get new measurements, repeat the optimization. And so on ...

LINEAR STOCHASTIC MODEL W/ DISCRETE DISTURBANCE

- Linear stochastic prediction model

$$\begin{cases} x_{k+1} &= A(\mathbf{w}_k)x_k + B(\mathbf{w}_k)u_k + f(\mathbf{w}_k) \\ y_k &= C(\mathbf{w}_k)x_k + g(\mathbf{w}_k) \end{cases}$$

possibly subject to stochastic output constraints $y_{\min}(\mathbf{w}_k) \leq y_k \leq y_{\max}(\mathbf{w}_k)$

- Stochastic discrete disturbance

$$w_k \in \{w^1, \dots, w^s\}$$

with discrete probabilities $p_j = \Pr [w_k = w^j], p_j \geq 0, \sum_{j=1}^s p_j = 1$

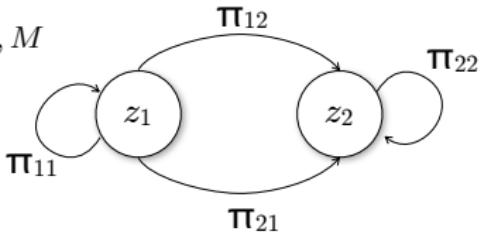

- (A, B, C) can be sparse matrices (e.g., network of interacting subsystems)
- Often w_k is low-dimensional (e.g., driver's power request, obstacle velocities, electricity price, weather, ...)

LINEAR STOCHASTIC MODEL W/ DISCRETE DISTURBANCE

- Probabilities p_j can be time varying, $p_j(t)$, and have their own dynamics

Example: Markov chain

$$\pi_{ih} = \Pr[z(t+1) = z_h \mid z(t) = z_i], \quad i, h = 1, \dots, M$$
$$p_j(t) = \begin{cases} e_{1j} & \text{if } z(t) = z_1 \\ \vdots & \vdots \\ e_{Mj} & \text{if } z(t) = z_M \end{cases}$$

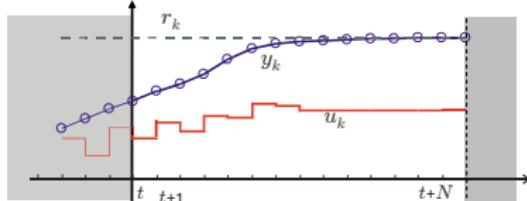

- Discrete distributions can be **estimated from historical data** (and adapted on-line)

COST FUNCTIONS FOR SMPC TO MINIMIZE

- Expected performance

$$\min_u \sum_{k=0}^{N-1} E_w [(y_k - r_k)^2]$$

- Tradeoff between expectation & risk

$$\min_u \sum_{k=0}^{N-1} (E_w [y_k - r_k])^2 + \alpha \text{Var}_w [y_k - r_k]$$

$$\alpha \geq 0$$

- Note that they coincide for $\alpha=1$, since

$$\text{Var}_w [y_k - r_k] = E_w [(y_k - r_k)^2] - (E_w [y_k - r_k])^2$$

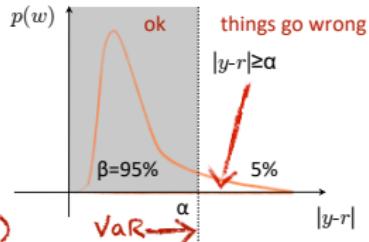

COST FUNCTIONS FOR SMPC TO MINIMIZE

- Conditional Value-at-Risk (CVaR) (Rockafellar, Uryasev, 2000)

$$\min_{u, \alpha} \sum_{k=0}^{N-1} \alpha_k + \frac{1}{1-\beta} E_w[\max\{|y_k - r_k| - \alpha_k, 0\}]$$

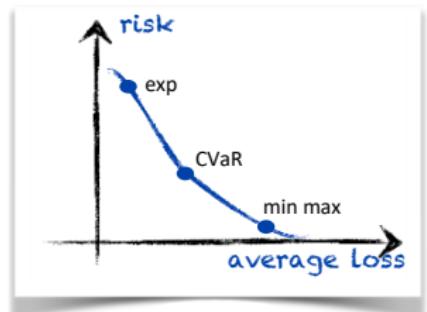

= minimize expected loss when things go wrong (convex !)

= expected shortfall

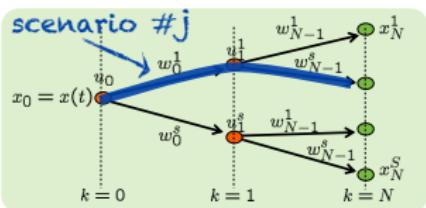

- Min-max = minimize worst case performance

$$\min_u \sum_{k=0}^{N-1} \max_w |y_k - r_k|$$

STOCHASTIC OPTIMAL CONTROL PROBLEM

- Enumerate all possible scenarios $\{w_0^j, w_1^j, \dots, w_{N-1}^j\}, j = 1, \dots, S$
- Scenario = path on the tree
- Number S of scenarios = number of leaf nodes

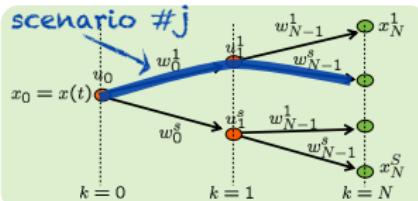

- Each scenario has probability $p_j = \prod_{k=0}^{N-1} \Pr[w_k = w_k^j]$

STOCHASTIC OPTIMAL CONTROL PROBLEM

- Each scenario has its own evolution

$$x_{k+1}^j = A(w_k^j)x_k^j + B(w_k^j)u_k^j + f(w_k^j)$$

(=linear time-varying system)

- Expectations become simple sums!

Example:

$$\min E_w \left[x_N' P x_N + \sum_{k=0}^{N-1} x_k' Q x_k + u_k' R u_k \right]$$

$$\min \sum_{j=1}^S p^j \left((x_N^j)' P x_N^j + \sum_{k=0}^{N-1} (x_k^j)' Q x_k^j + (u_k^j)' R u_k^j \right)$$

Expectations of quadratic costs remain quadratic costs

STOCHASTIC OPTIMAL CONTROL PROBLEM

- CVaR optimization (Rockafellar, Uryasev, 2000)

$$\min_{u,\alpha} \sum_{k=0}^{N-1} \alpha_k + \frac{1}{1-\beta} E_w [\max \{|y_k - r_k| - \alpha_k, 0\}]$$

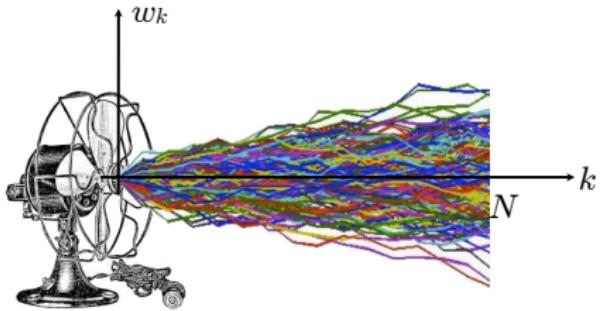

$$\begin{aligned} & \min_{u,z,\alpha} \sum_{k=0}^{N-1} \alpha_k + \frac{1}{1-\beta} \sum_{j=1}^S p^j z_k^j \\ \text{s.t. } & z_k^j \geq y_k^j - r_k^j - \alpha_k \\ & z_k^j \geq r_k^j - y_k^j - \alpha_k \\ & z_k^j \geq 0 \end{aligned}$$

CVaR optimization becomes a linear programming problem

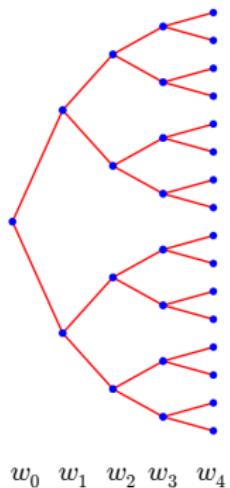

SCENARIO TREE GENERATION FROM DATA

- Scenario trees can be generated by **clustering** sample paths
- Paths can be obtained by **Monte Carlo simulation** of (estimated) models, or from **historical data**
- The **number of nodes** can be decided a priori

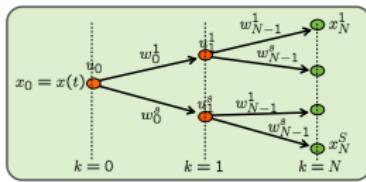

**Heuristic
Multilevel
Clustering**

(Heitsch, Römisch, 2009)

- **Alternatives** (simpler but less accurate): use histograms (only for $w_k \in \mathbb{R}$) or **K-means** (also in higher dimensions), within a recursive algorithm

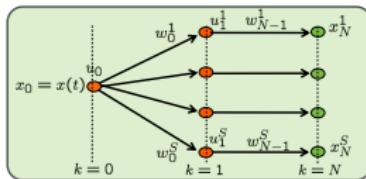

FREE CONTROL VARIABLES

Stochastic control (scenario tree)

Causality constraints: $u_k^j = u_k^h$ when scenarios j and h share the same node at prediction time k (in particular, $u_0^j \equiv u_0$ at root node $k = 0$)

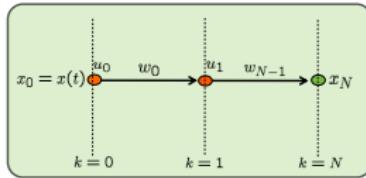

Decision u_k only depends on past disturbance realizations w_0, \dots, w_{k-1}

Stochastic control (scenario fan)

No causality in prediction: only $u_0^j \equiv u_0$ at root node.

Decision u_k depends on future disturbance realizations.

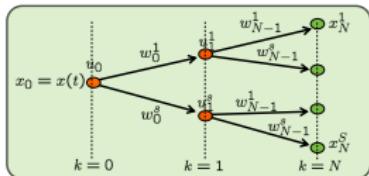

Deterministic control (single disturbance sequence)

- frozen-time: $w_k \equiv w(t), \forall k$ (causal prediction)
- prescient: $w_k = w(t+k)$ (non-causal)
- certainty equivalence: $w_k = E[w(t+k|t)]$ (causal)

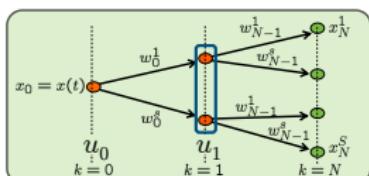

Tradeoff between **complexity** (=number of nodes) and **performance** (=accuracy of stochastic modeling)

OPEN-LOOP VS CLOSED-LOOP PREDICTION

closed-loop prediction

A different move u_k is optimized to counteract each outcome of the disturbance w_k

open-loop prediction

Only a sequence of inputs u_0, \dots, u_{N-1} is optimized, the same u_k must be good for all possible disturbances w_k

- Intuitively: OL prediction is more conservative than CL in handling constraints
- OL problem = CL problem + additional constraints (=less degrees of freedom)

LINEAR STOCHASTIC MPC FORMULATION

- A rich literature on stochastic MPC is available

(Schwarze, Nikolaou, 1999) (Munoz de la Pena, Bemporad, Alamo, 2005) (Primbs, 2007)
(Oldewurtel, Jones, Morari, 2008) (Wendt, Wozny, 2000) (Couchman, Cannon, Kouvaritakis, 2006)
(Ono, Williams, 2008) (Batina, Stoorvogel, Weiland, 2002) (van Hessem, Bosgra 2002)
(Bemporad, Di Cairano, 2005) (Bernardini, Bemporad, 2012)

See also recent survey (Mesbah, 2016)

- Performance index: $\min E_w \left[x'_N Px_N + \sum_{k=0}^{N-1} x'_k Q x_k + u'_k R u_k \right]$
- Goal: ensure **mean-square convergence** $\lim_{t \rightarrow \infty} E[x'(t)x(t)] = 0 \quad (f(w(t)) = 0)$
- Mean-square stability ensured by **stochastic Lyapunov function** $V(x) = x'Px$

$$E_{w(t)} [V(x(t+1))] - V(x(t)) \leq -x'(t)Lx(t), \forall t \geq 0$$

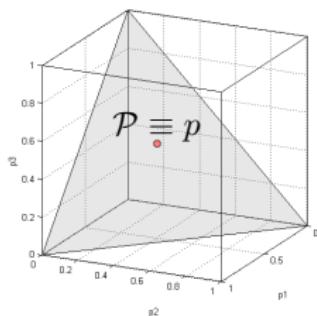

$$\begin{aligned} P &= P' \succ 0 \\ L &= L' \succ 0 \end{aligned}$$

(Morozan, 1983)

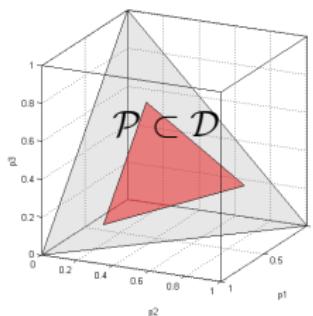

ROBUST LINEAR STOCHASTIC STABILIZATION

- The approach can be generalized to uncertain probabilities $p(t) \in \mathcal{P}$
(Example: time-varying probabilities)

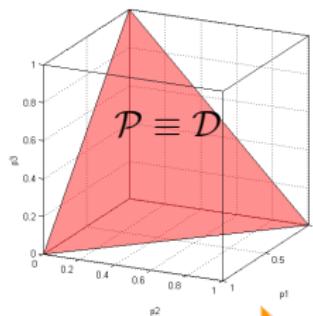

probability distribution is known

uncertain or time-varying probability distribution

no probability distribution is known, $w(t)$ can vary arbitrarily

Conservativeness

- If $\mathcal{P} \equiv \mathcal{D}$ we have a **robust** control problem (*robust convergence*)
- The more information we have about the probability distribution $p(t)$ of $w(t)$ the less conservative is the control action

STABILIZING STOCHASTIC MPC

(Bernardini, Bemporad, 2012)

- Impose stochastic stability constraint in SMPC problem
(=quadratic constraint w.r.t. u_0)

$$\begin{aligned} \min_u \quad & E_w \left[\sum_{k=0}^{N-1} \ell(x_k, u_k) \right] \\ \text{s.t.} \quad & x_{k+1} = A(w_k)x_k + B(w_k)u_k \\ & E[V(A(w_0)x_0 + B(w_0)u_0)] \leq x'_0(Q^{-1} - L)x_0 \\ & x_0 = x(t) \end{aligned}$$

performance and stability are decoupled

- SMPC approach:

- Solve LMI problem off-line to find stochastic Lyapunov fcn $V(x) = x'Q^{-1}x$
- Optimize stochastic performance based on scenario tree

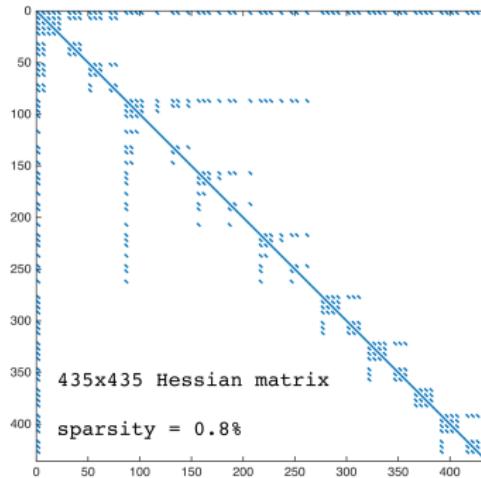

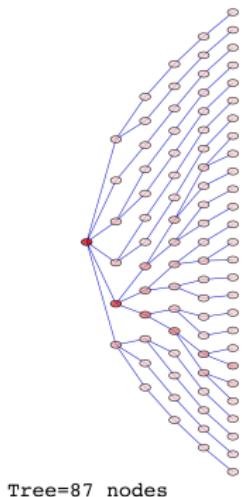

Theorem: The closed-loop system is as. stable in the mean-square sense

- SMPC can be generalized to handle **input and state constraints**

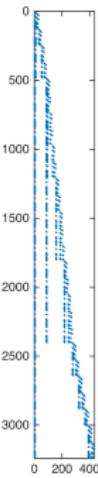

Note: recursive feasibility guaranteed by backup solution $u(k) = Kx(k)$

COMPLEXITY OF STOCHASTIC OPTIMIZATION PROBLEM

- #optimization variables = #nodes x #inputs (in condensed version)
- Problems are **very sparse** (well exploited by **interior point methods**)
- Example: SMPC with quadratic cost and linear constraints

435 free variables (5 inputs x node)

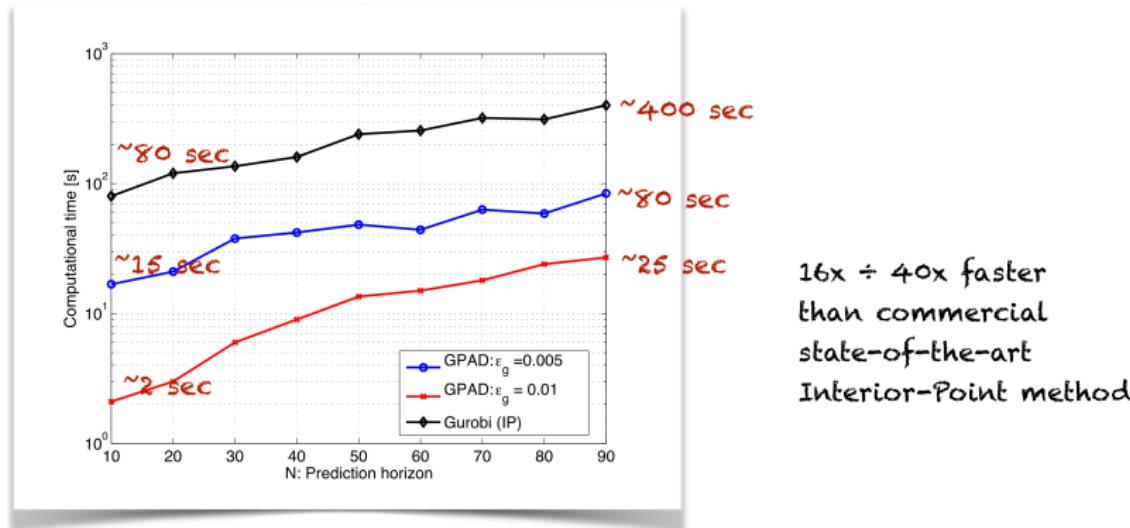

3240x435 constraint matrix
sparsity = 1.1%

DISTRIBUTED GPAD FOR STOCHASTIC MPC

- A distributed (parallelized) variant of the Accelerated Gradient Projection applied to Dual (GPAD) for solving SMPC problems is available

(Sampathirao, Sopasakis, Bemporad, 2014)

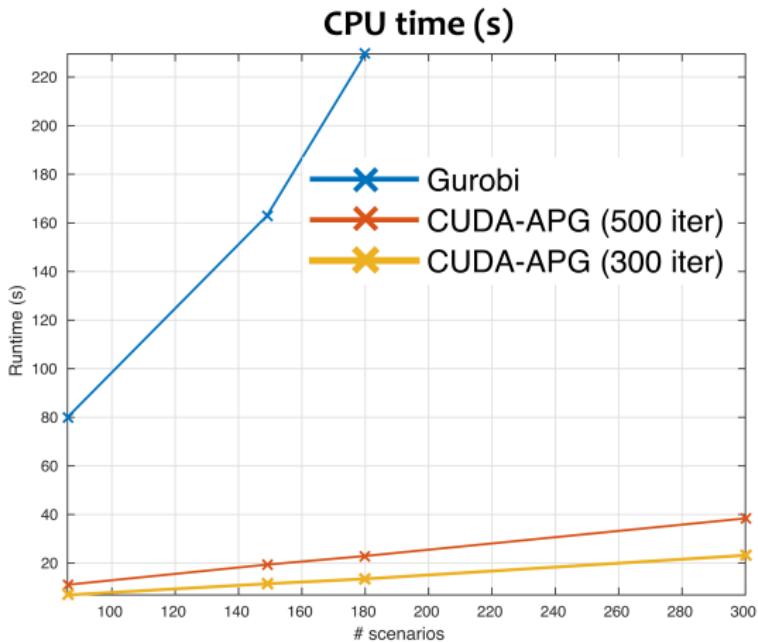

Example: stochastic MPC with **60 states, 25 inputs, 256 scenarios**

Remark: For larger problems (e.g., 50 states, 30 inputs, 9036 nodes)
GUROBI gets stuck on a 4GB 4-core PC, while dGPAD can solve the problem

DISTRIBUTED GPAD FOR STOCHASTIC MPC

(Sampathirao, Sopasakis, Bemporad, 2015)

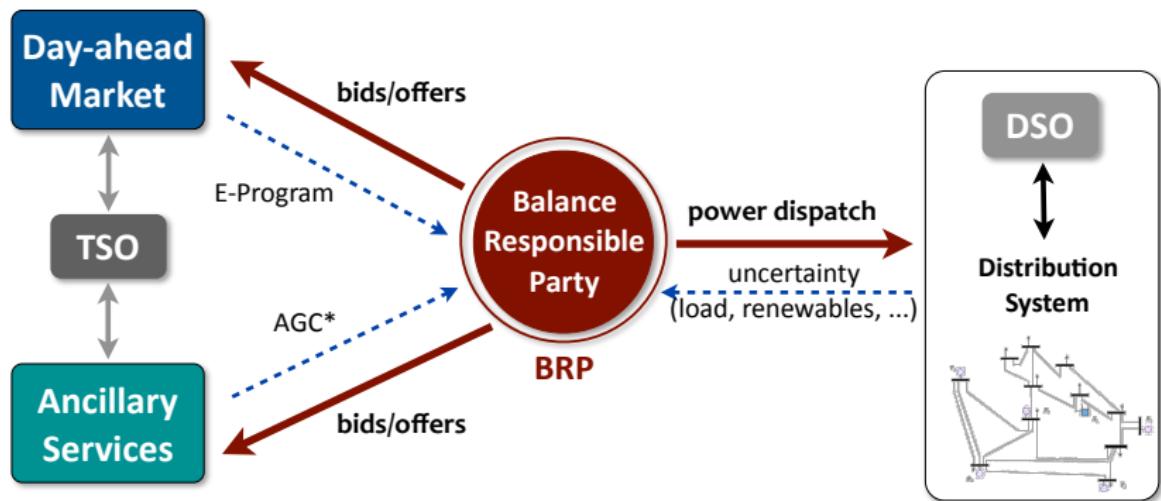

APG = Accelerated Proximal Gradient, parallel implemented
on NVIDIA Tesla 2075 CUDA platform

A FEW SAMPLE APPLICATIONS OF SMPC

- **Energy systems:** power dispatch in smart grids, optimal bidding on electricity markets
(Patrinos, Trimboli, Bemporad 2011)
(Puglia, Bernardini, Bemporad 2011)
- **Financial engineering:** dynamic hedging of portfolios replicating synthetic options
(Bemporad, Bellucci, Gabbiellini, 2009)
(Bemporad, Gabbiellini, Puglia, Bellucci, 2010)
(Bemporad, Puglia, Gabbiellini, 2011)
- **Water networks:** pumping control in urban drinking water networks, under uncertain demand & minimizing costs under varying electricity prices
(Sampathirao, Sopasakis, Bemporad, 2014)
- **Automotive control:** energy management in HEVs, adaptive cruise control (human-machine interaction)
(Di Cairano, Bernardini, Bemporad, Kolmanovsky, 2014)
- **Networked control:** improve robustness against communication imperfections
(Bernardini, Donkers, Bemporad, Heemels, NECSYS 2010)

SMPC FOR REAL-TIME OPTIMAL POWER DISPATCH

SMPc FOR OPERATING ON ENERGY MARKETS

Objective: maximize BRP's profit !

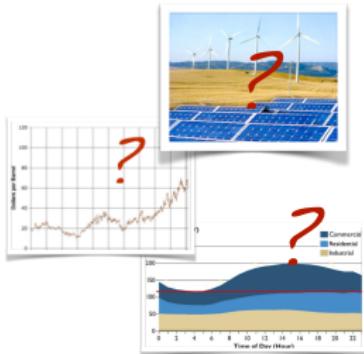

while satisfying local power demand
and all grid constraints

*AGC = Automatic Generation Control

REAL-TIME POWER DISPATCH PROBLEM

- Balance Responsible Parties (BRPs) participate to the various energy markets and trade electricity to satisfy their loads and make profits
- Optimal control of BRPs is challenging, as in **real-time** a BRP must
 - fulfill its E-Program, despite perturbations induced by **uncertainties**
 - intermittent generation from renewable sources
 - time-varying internal loads
 - react to signals arriving from the TSO
 - frequency deviations, AS bids activated by the TSO
 - minimize generation and imbalance **costs**
 - time-varying, stochastic imbalance prices
 - consider plant **dynamics** and satisfy **constraints**
 - bounds on power output, **ramp-rate constraints**

SMPc FOR REAL-TIME MARKET-BASED POWER DISPATCH

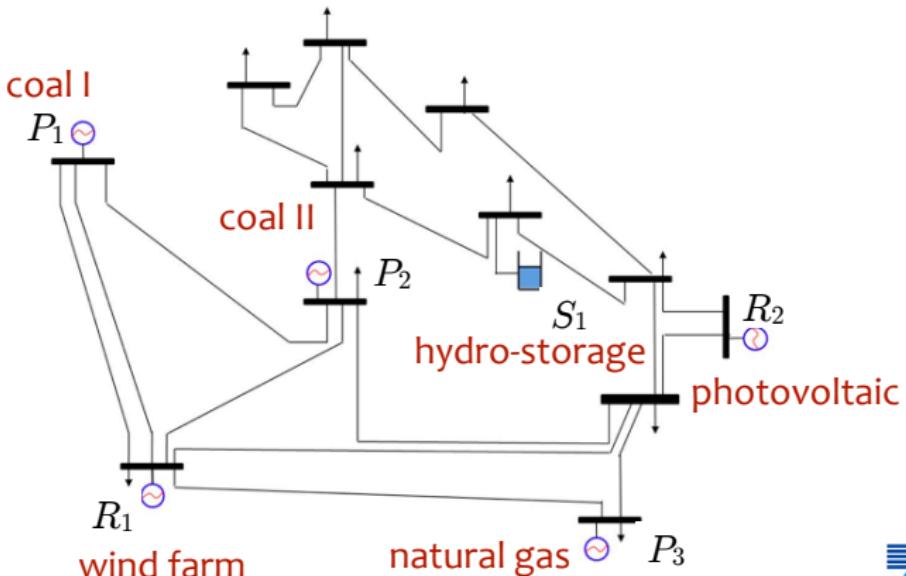

(Patrinos, Trimboli, Bemporad, 2011)

- We are a legal entity (BRP) trading on the energy (PX) and ancillary service (AS) markets
- **Objective:** Minimize costs via efficient use of intermittent resources, and maximize profits by trading on electricity (PX, AS) markets
- **Constraints:** Grid capacity, rate limits, load balancing, AS balancing

POWER DISPATCH MODEL

(Patrinos, Trimboli, Bemporad, 2011)

- Microgrid with three conventional power generators (P_1, P_2, P_3), two renewables (R_1, R_2), one storage system (S_1), satisfying local load and exchanging power with the grid

POWER DISPATCH MODEL

- Conventional generator model ($i=1,2,3$)

power generated
at next time unit

$$P_{i,k+1} = P_{i,k} + \Delta P_{i,k}$$

constraints on generated power:

$$P_{i,\min} \leq P_{i,k} \leq P_{i,\max}$$

constraints on power variation:

$$\Delta P_{i,\min} \leq \Delta P_{i,k} \leq \Delta P_{i,\max}$$

- Storage model

α = self discharge loss

α_c = charge efficiency

α_d = discharge efficiency

$$S_{k+1} = \alpha S_k + \alpha_c u_{c,k} - \frac{1}{\alpha_d} u_{d,k}$$

constraints on charge/discharge:

$$S_{\min} \leq S_k \leq S_{\max}$$

constraints on charge/discharge rate:

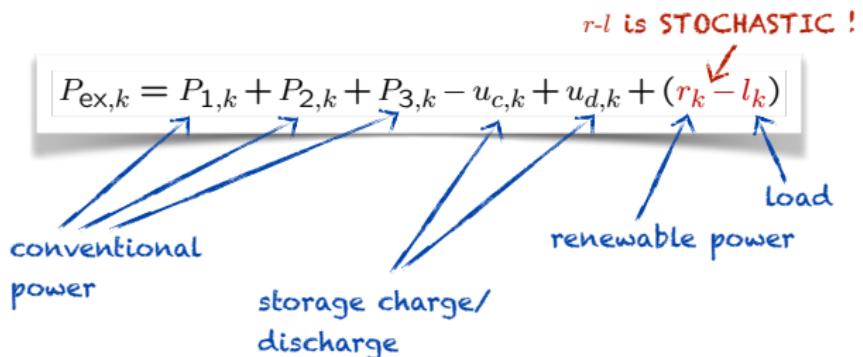

$$\Delta S_{\min} \leq S_{k+1} - S_k \leq \Delta S_{\max}$$

constraints on power flows:

$$0 \leq u_{c,k} \leq u_{c,\max}, \quad 0 \leq u_{d,k} \leq u_{d,\max}$$

POWER DISPATCH MODEL

- Power exchanged with the rest of the grid (=balance)

- Overall linear model and constraints

$$x = \begin{bmatrix} P_1 \\ P_2 \\ P_3 \\ S \end{bmatrix} \quad u = \begin{bmatrix} \Delta P_1 \\ \Delta P_2 \\ \Delta P_3 \\ u_c \\ u_d \\ r - l \end{bmatrix} \quad y = \begin{bmatrix} P_{ex} \\ P_1 \\ P_2 \\ P_3 \\ S \\ \Delta S \end{bmatrix}$$

uncontrolled input

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & \alpha \end{bmatrix} \quad B = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \alpha_c & -\frac{1}{\alpha_d} & 0 \end{bmatrix}$$

$$C = \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & \alpha - 1 \end{bmatrix} \quad D = \begin{bmatrix} 0 & 0 & 0 & -1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \alpha_c & -\frac{1}{\alpha_d} & 0 \end{bmatrix}$$

POWER DISPATCH COST FUNCTION

- Cost function: terms to penalize

electricity price on
RT market (STOCHASTIC)

$$\min \sum_{k=0}^{N-1} \gamma(P_{\text{ex},k} - E_k)^2 + (a_i P_{i,k}^2 + b_i P_{i,k} + c_i) + p_k P_{\text{ex},k}$$

penalty on deviation
from E-program

production cost from
conventional plants

price to pay to get
power from RT market

$E_k = 0, \gamma = 0$ if no E-Program is agreed on the day-ahead market

- The overall linear MPC problem maps into a QP:

$$\min_z \frac{1}{2} z' H z + \left(F \begin{bmatrix} x_0 \\ r-l \\ E \end{bmatrix} + c \right) z + d$$

x_0 = current state
 $r-l$ = predicted renewable power - load
 E = E-program

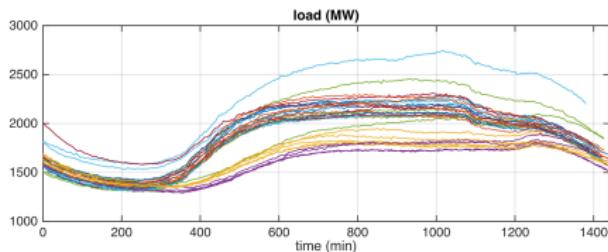

$$\text{s.t. } Gz \leq W + S \begin{bmatrix} x_0 \\ r-l \\ E \end{bmatrix}$$

$$z = \{ \Delta P_{i,k}, u_{c,k}, u_{d,k} \}_{k=0}^{N-1}$$

SMPc FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Historical data of load (MW)

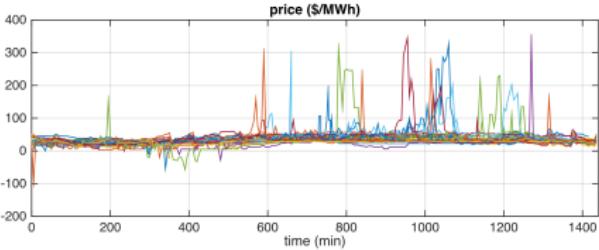

load = 1/3 load of N.Y.C. district
(daily data of 1-31 May 2014,
sampling time = 5 min)

http://www.nyiso.com/public/markets_operations/market_data/load_data/index.jsp

- Historical data of price (MW)

electricity price of N.Y.C. district
(daily data of 1-31 May 2014,
sampling time = 5 min)

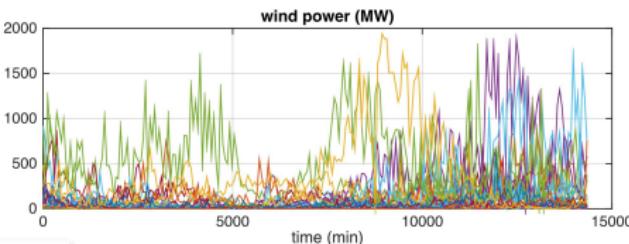

http://www.nyiso.com/public/markets_operations/market_data/pricing_data/index.jsp

SMPc FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Historical data of wind speed (m/s)

Station BGNN4 (NY)
(daily data of 1-31 May 2014,
sampling time = 6 min)

wind power proportional
to cubic wind velocity

$$P_w = k v_w^3$$

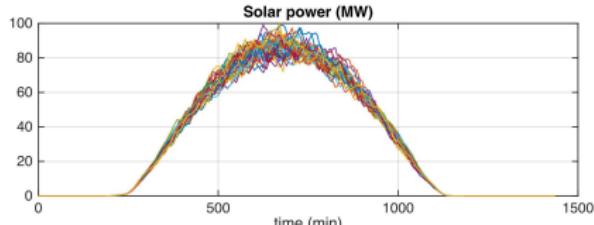

http://www.ndbc.noaa.gov/station_history.php?station=bgnn4

- Historical data of solar irradiation (W/m²)

NY Central Park, daily data of
1-31 May 1991-2005, sampling time = 1 h

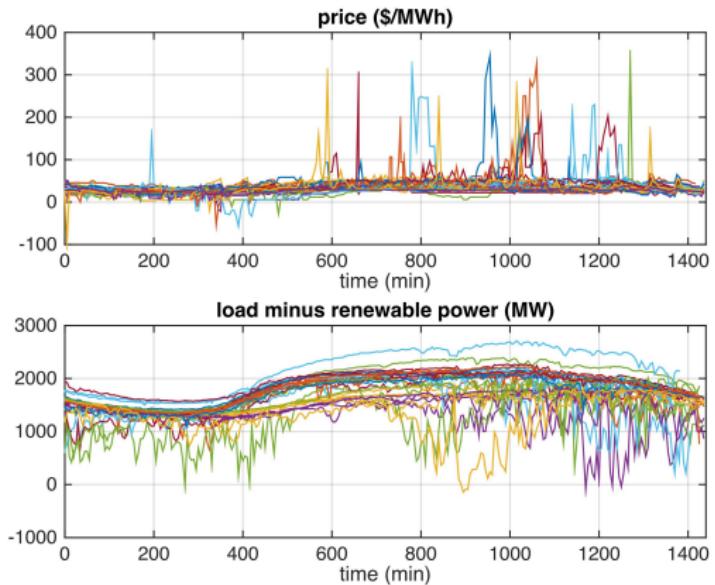

Data perturbed by noise to mimic
account cloud coefficient (unavailable)

<http://en.openei.org/datasets/files/39/pub/725033.tar.gz>

SMPG FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Historical data of overall uncertainty

SMPC FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Data used for scenario generation (31 days):

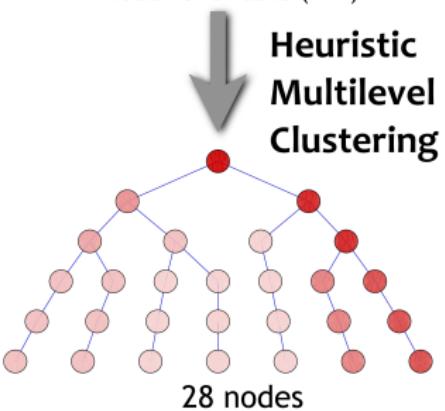

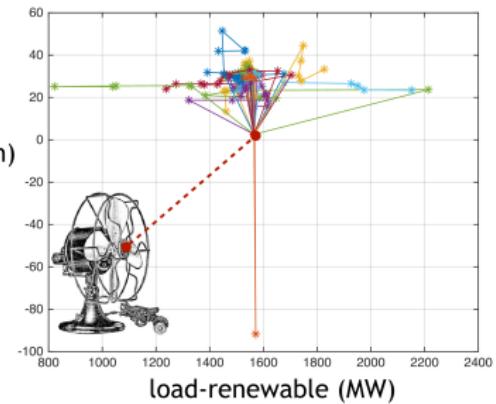

$$w^j(t+k) = v^j(t+k) - v^j(t) + v(t)$$

value at time $t+k$ in scenario # j

initial value at time t in scenario # j

stochastic vector on scenario # j

actual value at time t

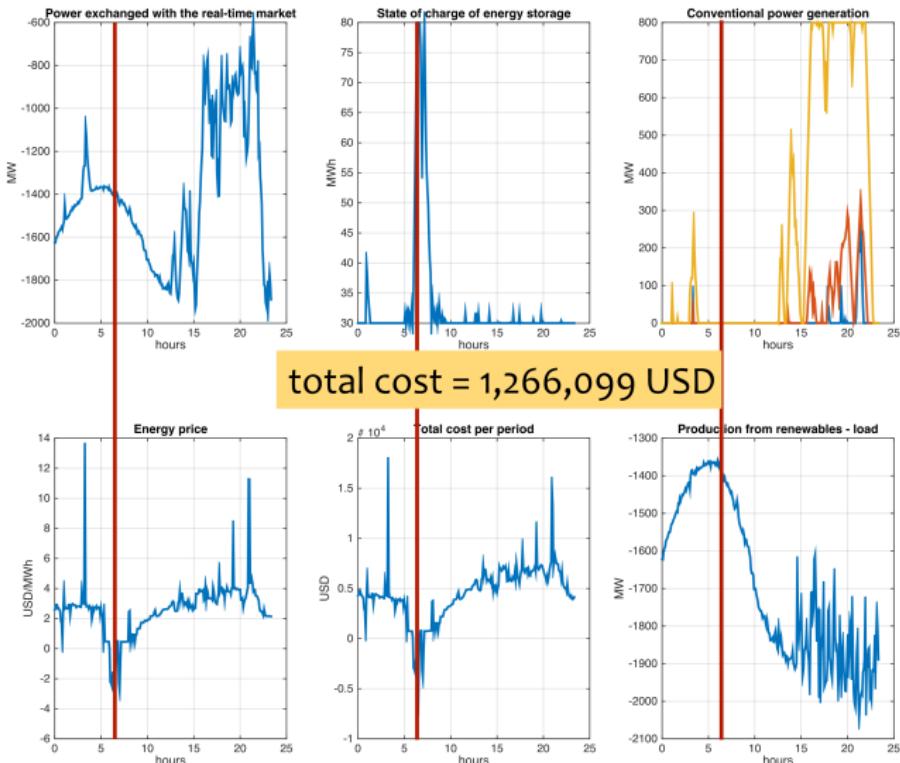

- Tree obtained from 31 scenarios
(branching factor $M=[2\ 2\ 2\ 1\ 1]$)

SMPC FOR MARKET-BASED OPTIMAL POWER DISPATCH

- MPC setup:
 - Sampling time: $T_s=5$ min
 - Prediction horizon: $N=6$ steps (=1/2 hour ahead)
 - Three controller options:
 - **Stochastic MPC**, with branching factor M (ex: $M=[4\ 3\ 2\ 2\ 1]$)
 - **Average MPC**, that is deterministic MPC based on the **expected** (price, load-renewable) realization
 - **Prescient MPC**, that is deterministic MPC based on the **exact** future (price, load-renewable) realization

SMPG FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Simulation results using SMPC, $M=[2,2,2,1,1]$ (1 day, May 26, 2014)

SMPc FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Compare simulation results wrt different tree complexity, prescient, and deterministic (1 day, May 26, 2014)

exact knowledge
of future uncertainty

stochastic formulation

Prescient:	Total cost= 1,247,909 [USD],	nvar= 30, CPUTIME = 14 [ms]
Stochastic:	Total cost= 1,266,095 [USD], M=[2,2,2,1,1], nvar= 105, CPUTIME = 43 [ms]	
Stochastic:	Total cost= 1,266,123 [USD], M=[3,3,1,1,1], nvar= 140, CPUTIME = 50 [ms]	
Stochastic:	Total cost= 1,266,214 [USD], M=[2,2,1,1,1], nvar= 95, CPUTIME = 30 [ms]	
Stochastic:	Total cost= 1,266,701 [USD], M=[3,1,1,1,1], nvar= 80, CPUTIME = 27 [ms]	
Stochastic:	Total cost= 1,267,069 [USD], M=[2,1,1,1,1], nvar= 55, CPUTIME = 22 [ms]	
Average:	Total cost= 1,267,113 [USD], M=[1,1,1,1,1] nvar= 30, CPUTIME = 14 [ms]	
Frozen-time:	Total cost= 1,267,401 [USD], nvar= 30, CPUTIME = 14 [ms]	

deterministic: assume
future disturbance =
average of historical
data

deterministic: assume
future disturbance =
current disturbance

nvar = number of variables in QP problem = 5*(# nodes), CPUTIME = time to build tree, build QP matrices, and solve

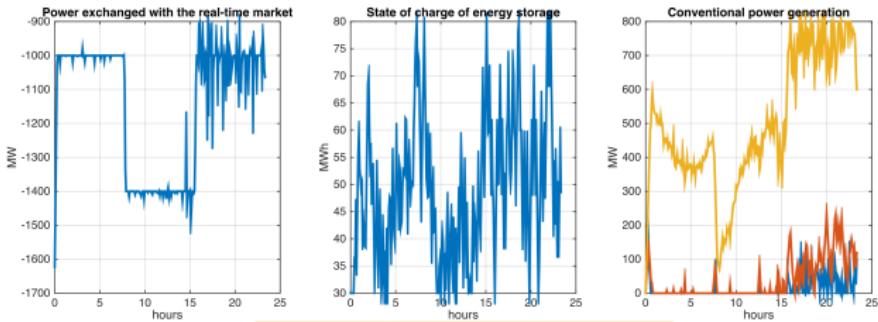

SMPC FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Tracking an E-Program

$$\gamma = 10^3$$

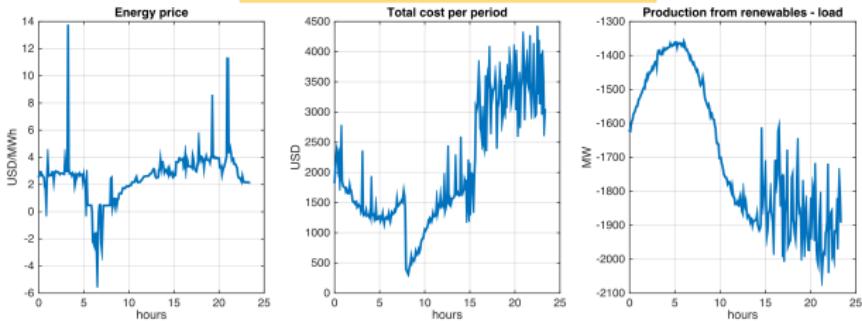

SMPC with branching factor M=[2 2 2 1 1]

$$\min \sum_{k=0}^{N-1} \gamma (P_{\text{ex},k} - E_k)^2 + (a_i P_{i,k}^2 + b_i P_{i,k} + c_i) - p_k [P_{\text{ex},k} - E_k]$$

total cost = 574,388 USD

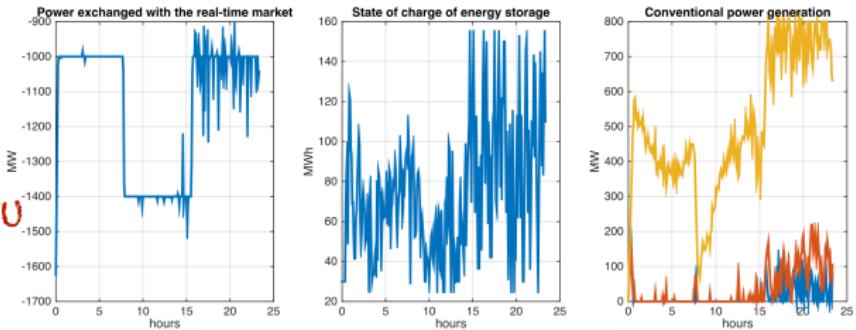

Revenues from day-ahead market are not counted

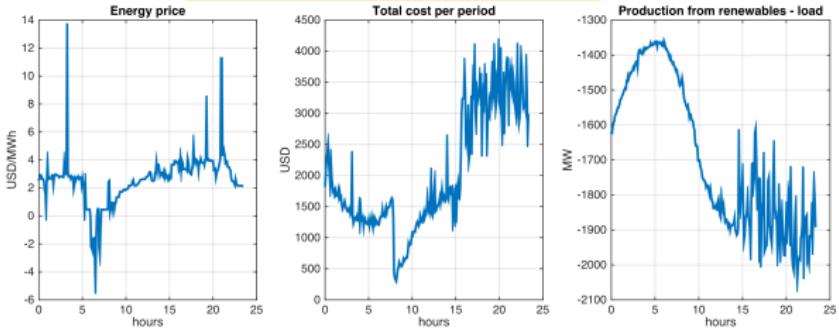

SMPc FOR MARKET-BASED OPTIMAL POWER DISPATCH

- Change storage type: $S_{\min} \leq S_k \leq S_{\max}$ $\Delta_{S,\min} \leq S_{k+1} - S_k \leq \Delta_{S,\max}$

$$\begin{aligned}S_{\min} &= 30 \\S_{\max} &= 80 \quad 150 \text{ MWh} \\ \Delta_{S,\min} &= -10 \quad \pm 40 \\ \Delta_{S,\max} &= 10 \quad \text{MWh/PTU}\end{aligned}$$

total cost = 563,283 USD

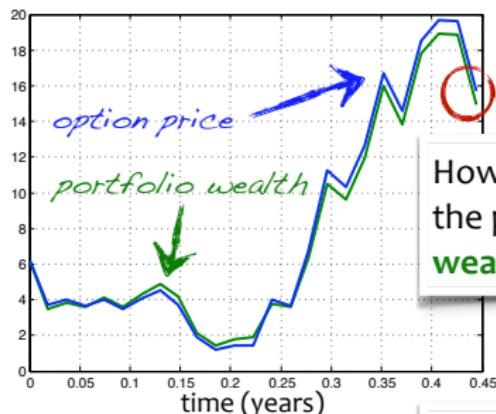

Revenues from day-ahead market are not counted

SMPC FOR DYNAMIC HEDGING OF FINANCIAL OPTIONS

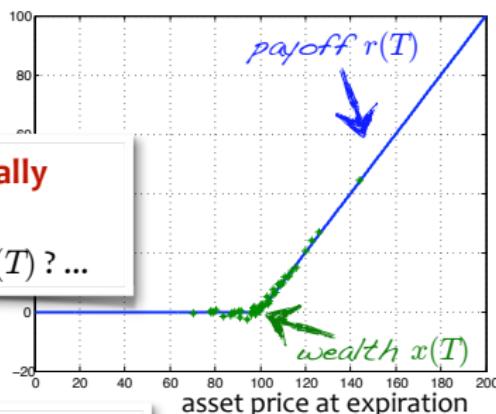

DYNAMIC HEDGING PROBLEM FOR FINANCIAL OPTIONS

- The financial institution sells a **synthetic option** to a customer and gets $x(0)$ (€)
- Such money $x(0)$ is used to create a **portfolio** $x(t)$ of n underlying **assets** (e.g., stocks) whose prices at time t are $w_1(t), w_2(t), \dots, w_n(t)$
- At the **expiration date** T , the option is worth the **payoff** $r(T) = \text{wealth}$ (€) to be returned to the customer

How to **adjust dynamically**
the portfolio so that
wealth $x(T) = \text{payoff}$ $r(T)$? ...

.. for any price realization $w_i(t)$?

PORTFOLIO DYNAMICS

- Portfolio wealth at time t :

$$x(t) = u_0(t) + \sum_{i=1}^n w_i(t)u_i(t)$$

money in bank account
(risk-free asset)

price of asset #i
(stochastic process)

number of assets #i

Example: $w_i(t) = \text{log-normal}$ model (used in Black-Scholes' theory)

$$dw_i = (\mu dt + \sigma dz_i)w_i \quad \text{geometric Brownian motion}$$

- Assets traded at **discrete-time** intervals under the **self-balancing constraint**:

$$\rightarrow x(t+1) = (1+r)x(t) + \sum_{i=0}^n b_i(t)u_i(t) \quad r = \text{interest rate}$$

$b_i(t) \triangleq w_i(t+1) - (1+r)w_i(t)$

PAYOUT FUNCTION

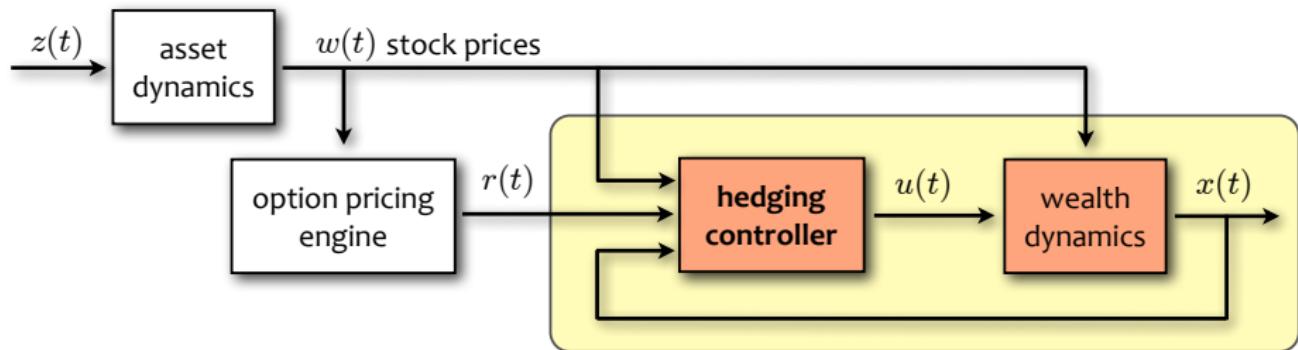

- **Stochastic disturbance:** $w(t) = [w_1(t) \dots w_n(t)]'$ (=asset prices)
- **Reference signal:** option price $p(t)$. This may depend only on $w(t)$, or also on previous prices $w(0), \dots, w(t-1)$
- Similarly $p(T)$ may either depend only on $w(T)$ or also on previous prices.
For example:
 - European call
 - Napoleon cliquet

$$p(T) = \max\{w(T), 0\}$$

$$p(T) = \max \left\{ 0, C + \min_{i \in \{1, \dots, N_{\text{fix}}\}} \frac{w(t_i) - w(t_{i-1})}{w(t_{i-1})} \right\} \quad (t_i = \text{fixing dates})$$

OPTION HEDGING = LINEAR STOCHASTIC CONTROL

- Block diagram of dynamic option hedging problem:

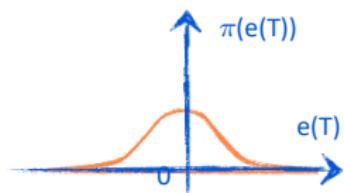

- Reference signal $r(t) = \text{price } p(t)$ of hedged option

- Control objective:** $x(T)$ should be as close as possible to $r(T)$, for any possible realization of the asset prices $w(t)$ (“tracking w/ disturbance rejection”)

CONTROL OBJECTIVE

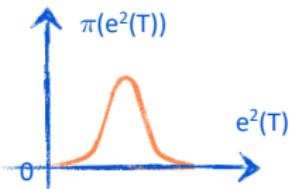

- **Tracking error** = hedging error $e(t) = x(t) - p(t)$

we want $e(T)$ small !

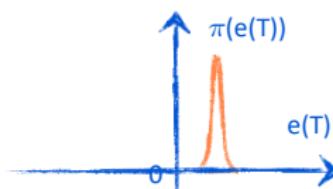

$$\min E [e(T)]^2$$

Very risky, variance of $e(T)$ may be Large !

$$\min E [e(T)^2]$$

If minimum is 0 then both mean and variance of hedging error are 0

$$\min E [(e(T) - E[e(T)])^2]$$

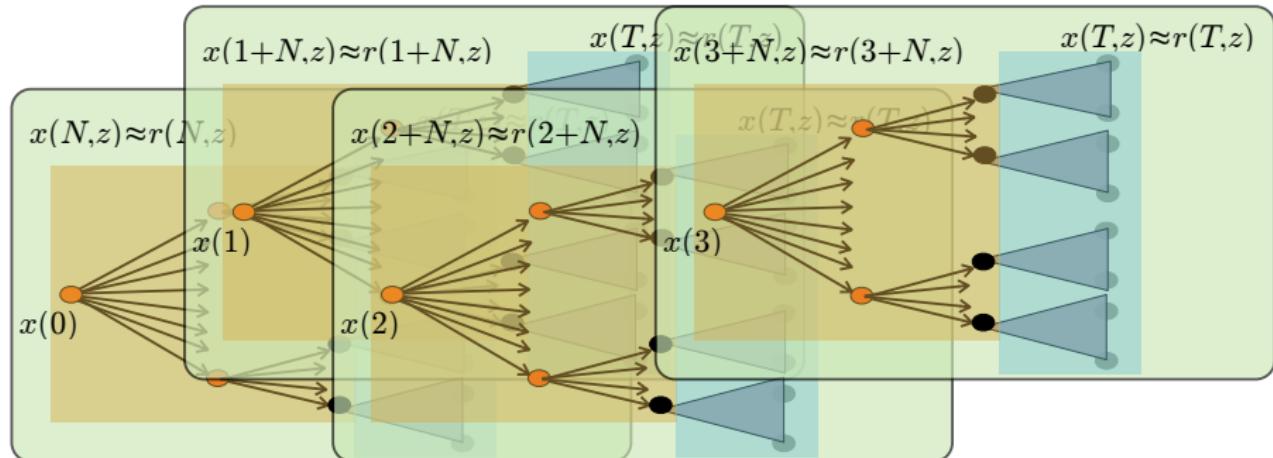

How about $E[e(T)]$?

- Recall: $E[e(T)^2] = \overbrace{E[(e(T) - E[e(T)])^2]}^{\text{Var}[e(T)]} + \alpha E[e(T)]^2$ for $\alpha = 1$
- Under non-arbitrage conditions, if variance is minimized and the minimum is zero then $E[e(T)] = 0$ (Bemporad, Bellucci, Gabbriellini, 2014)

SMPG FOR DYNAMIC OPTION HEDGING

- Stochastic finite-horizon optimal control problem:

$$\begin{aligned} \min_{\{u(k,z)\}} \quad & \text{Var}_z [x(t + N, z) - r(t + N, z)] \\ \text{s.t.} \quad & x(k + 1, z) = (1 + r)x(k, z) + \sum_{i=0}^n b_i(k, z)u_i(k, z), \quad k = t, \dots, t + N \\ & x(t, z) = x(t) \end{aligned}$$

SMPG FOR DYNAMIC OPTION HEDGING

- Drawback: the longer the horizon N , the largest the number of scenarios !

- Special case: use $N=1$!

*minimum
variance
control !*

$$\begin{array}{ll} \min_{u(t)} & \text{Var}_z [x(t+1, z) - r(t+1, z)] \\ \text{s.t.} & x(t+1, z) = (1+r)x(t) + \sum_{i=0}^n b_i(t, z)u_i(t) \end{array}$$

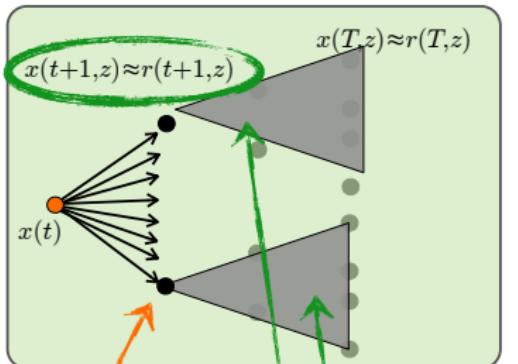

- ✓ Only one vector $u(t)$ to optimize

- ✓ No further branching, so we can generate a lot of scenarios for z ! (example: 1000)

- Need to compute target wealth $r(t+1, z)$ for all z

On-line optimization: very simple least squares problem with n variables !

(n = number of traded assets)

*Perfect hedging assumption
from time $t+1$ to T*
Optimize up to time $t+1$

SMPC HEDGING ALGORITHM

- Let t =current hedging date, $w(t)$ =wealth of portfolio, $x(t) \in \mathbb{R}^n$ = asset prices

- Use **Monte Carlo simulation** to generate M scenarios of future asset prices

$$x^1(t+1), x^2(t+1), \dots, x^M(t+1)$$
$$y^1(t+1), y^2(t+1), \dots, y^M(t+1)$$

- Use a **pricing engine** to generate the corresponding future option prices

$$p^1(t+1), p^2(t+1), \dots, p^M(t+1)$$

- Optimize** sample variance, get new asset quantities $u(t) \in \mathbb{R}^n$, rebalance portfolio:

$$\min_{u(t)} \sum_{j=1}^M \left(w^j(t+1) - p^j(t+1) - \left(\frac{1}{M} \sum_{i=1}^M w^i(t+1) - p^i(t+1) \right) \right)^2$$

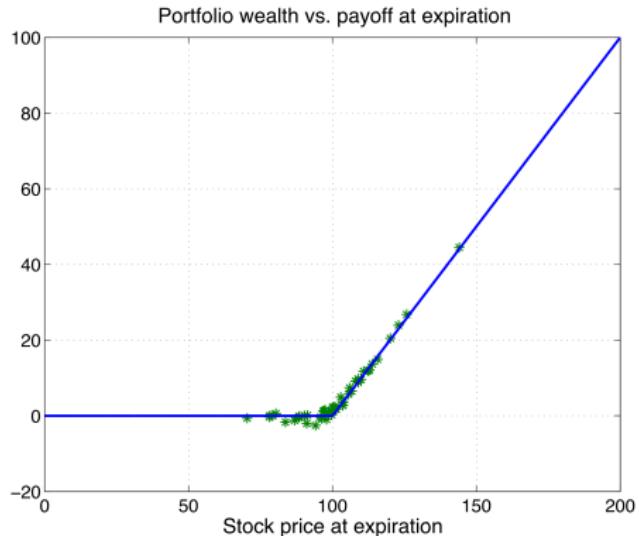

Least squares problem

(n = number of traded assets)

With **transaction costs**, the problem can be cast to a **quadratic program**

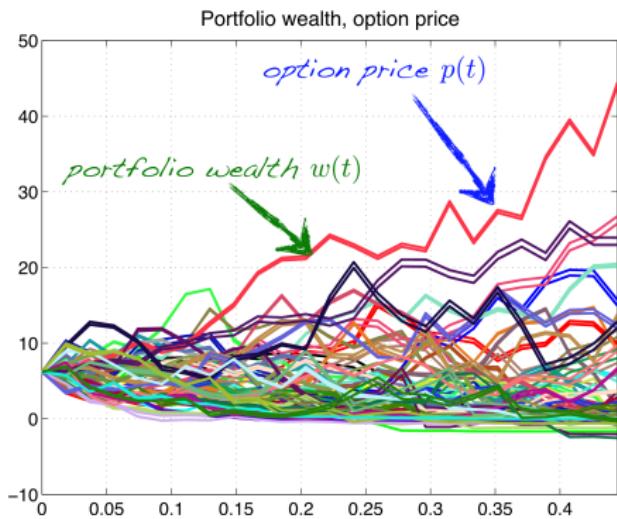

(Bemporad, Puglia, Gabbiellini, 2011)

EXAMPLE: BS MODEL, EUROPEAN CALL

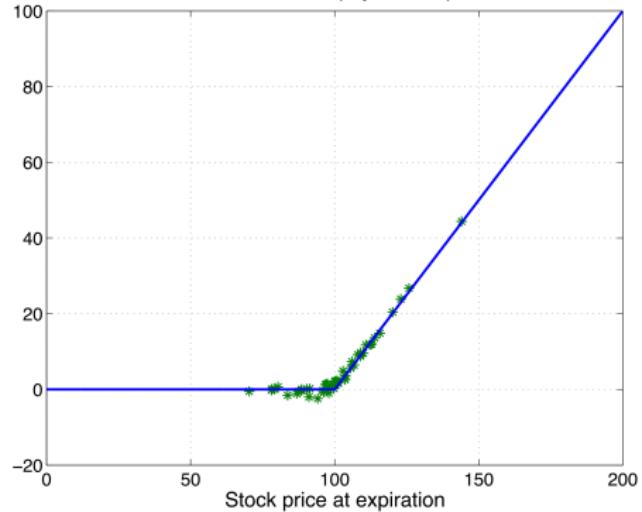

- CPU time = 7.52 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

- Black-Scholes model (=log-normal)
- volatility=0.2, risk-free=0.04
- $T=24$ weeks ($\Delta t=1$ week)
- 50 simulations
- $M=100$ scenarios
- Pricing method: Monte Carlo sim.
- SMPC**

EXAMPLE: BS MODEL, EUROPEAN CALL

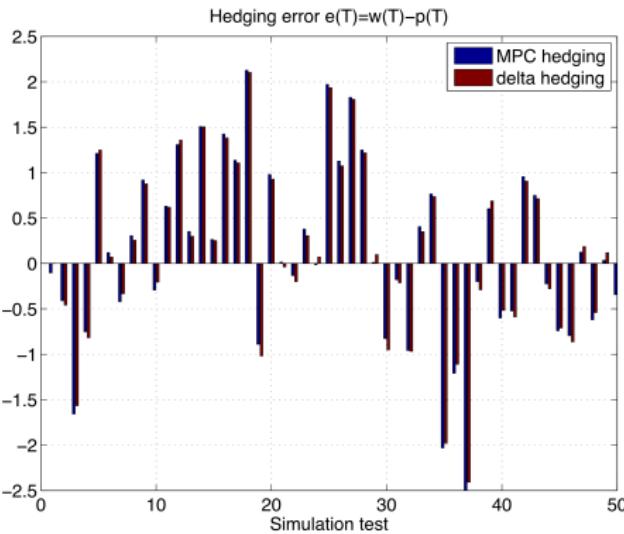

Portfolio wealth vs. payoff at expiration

- CPU time = 0.2 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

SMPC and delta-hedging are almost indistinguishable

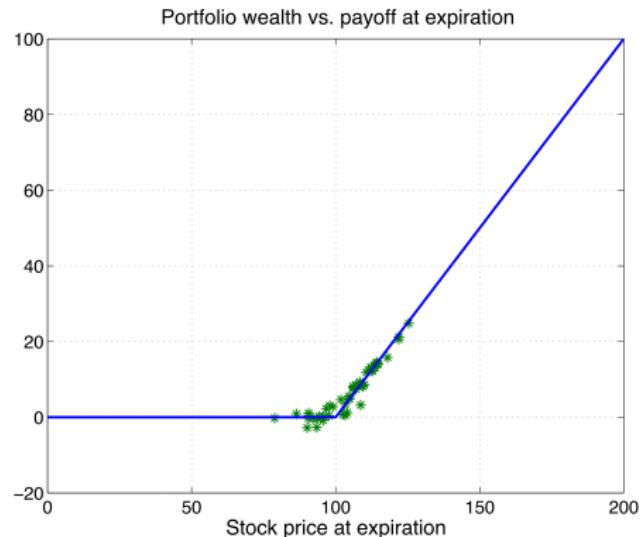

- Black-Scholes model (=log-normal)
- volatility=0.2, risk-free=0.04
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- **Delta-hedging**

EXAMPLE: BS MODEL, EUROPEAN CALL

EXAMPLE: HESTON MODEL, EUROPEAN CALL

- CPU time = 85.5 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

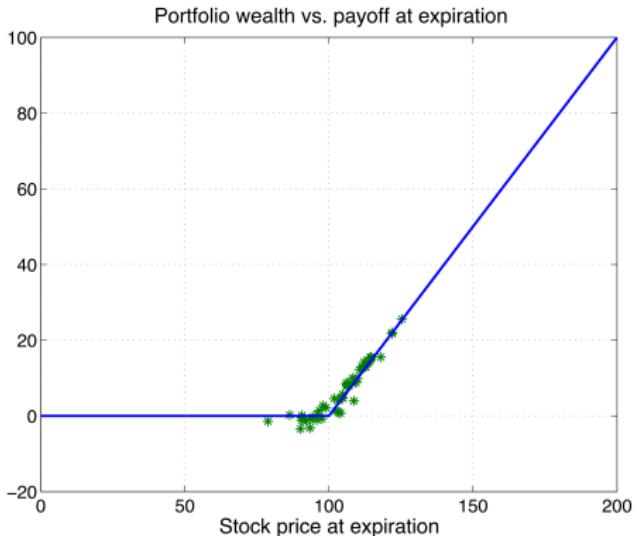

• Heston's model

- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- risk-free=0.04
- Pricing method: Monte Carlo sim.
- SMPC

Heston's model

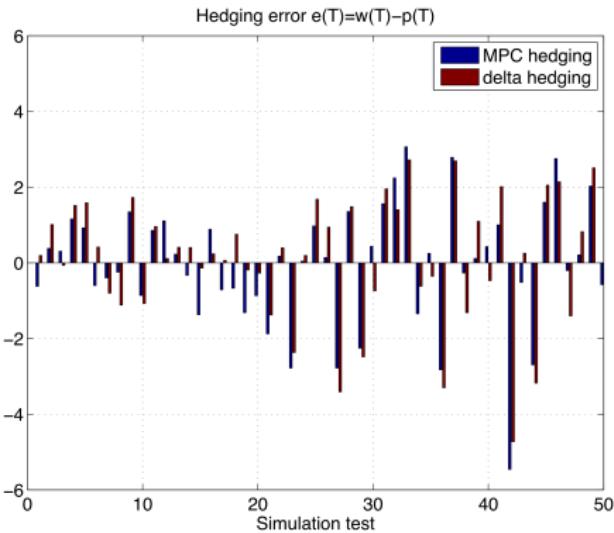

$$\begin{aligned}dx_i(\tau) &= (\mu_i^x d\tau + \sqrt{y_i(\tau)} dz_i^x) x_i(\tau) \\dy_i(\tau) &= \theta_i(k_i - y_i(\tau)) d\tau + \omega_i \sqrt{y_i(\tau)} dz_i^y\end{aligned}$$

EXAMPLE: HESTON MODEL, EUROPEAN CALL

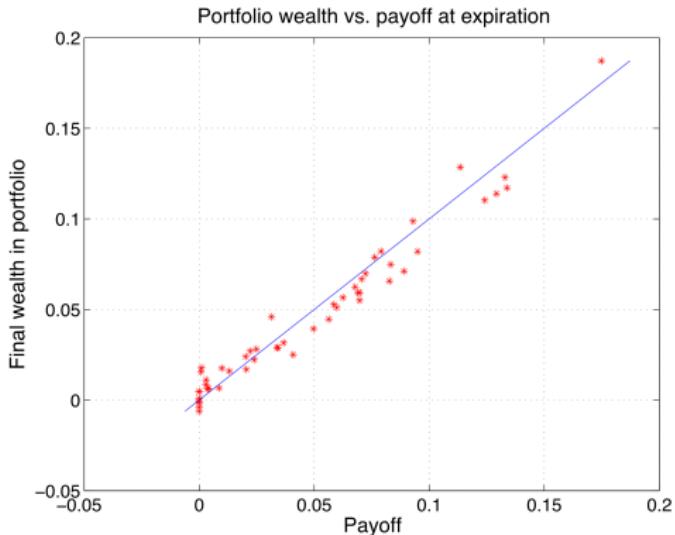

- CPU time = 1.85 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

- Heston's model
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- risk-free=0.04
- **Delta hedging**

EXAMPLE: BS MODEL, NAPOLEON CLIQUET

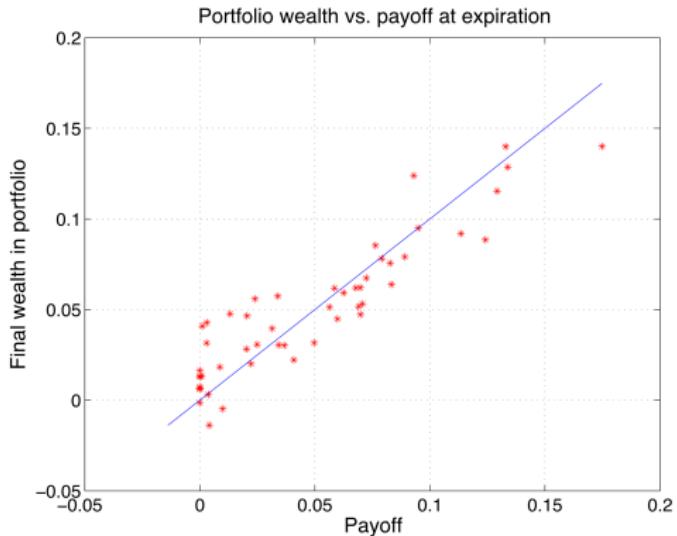

- Black-Scholes model (=log-normal)
- volatility=0.2
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- risk-free=0.04
- Pricing method: Monte Carlo sim.
- **SMPC: only trade underlying stock**

$$p(T) = \max \left\{ 0, C + \min_{i \in \{1, \dots, N_{\text{fix}}\}} \frac{x(t_i) - x(t_{i-1})}{x(t_{i-1})} \right\}$$

$t_i = 0, 8, 16, 24$ weeks

- CPU time = 1400 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

EXAMPLE: BS MODEL, NAPOLEON CLIQUET

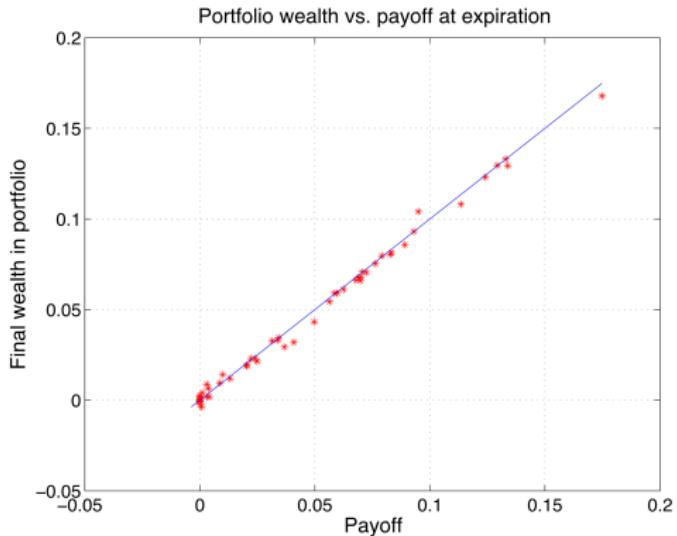

- Black-Scholes model (=log-normal)
- volatility=0.2
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- risk-free=0.04
- **Delta hedging,
only trade underlying stock**

$$p(T) = \max \left\{ 0, C + \min_{i \in \{1, \dots, N_{\text{fix}}\}} \frac{x(t_i) - x(t_{i-1})}{x(t_{i-1})} \right\}$$

- CPU time = 2.41 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

$t_i = 0, 8, 16, 24$ weeks

EXAMPLE: BS MODEL, NAPOLEON CLIQUET

- Black-Scholes model (=log-normal)
- volatility=0.2
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- risk-free=0.04
- Pricing method: Monte Carlo sim.
- **SMPC: Trade underlying stock & European call with maturity $t+T$**

$$p(T) = \max \left\{ 0, C + \min_{i \in \{1, \dots, N_{\text{fix}}\}} \frac{x(t_i) - x(t_{i-1})}{x(t_{i-1})} \right\}$$

$t_i = 0, 8, 16, 24$ weeks

- CPU time = 1625 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)

APPROXIMATE OPTION PRICING

- **Bottleneck** of the approach for exotic options: price M future option values $p^1(t+1), p^2(t+1), \dots, p^M(t+1)$
- **Monte Carlo pricing** can be time consuming: say L scenarios to evaluate a single option value \Rightarrow need to simulate ML paths to build optimization problem (e.g.: $M=100, L=10000, ML=10^6$)
- Use off-line **function approximation** techniques to estimate $p(t)$ as a function of current asset parameters and other option-related parameters

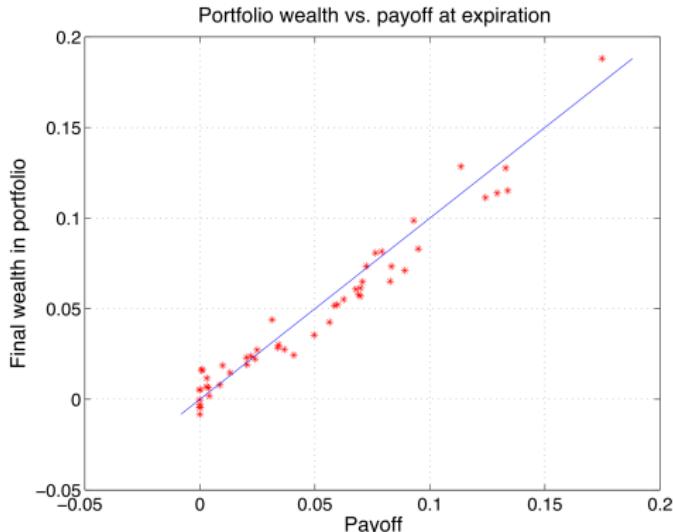

Example: Napoleon cliquet, Heston model

$$p(t) = f(x(t), \sigma(t), x(t_1), \dots, x(t_{N_{\text{fix}}}))$$

- Most suitable method for estimating pricing function f : **least-squares Monte Carlo** approach based on polynomial approximations

(Longstaff, Schwartz, 2001)

EXAMPLE: BS MODEL, NAPOLEON CLIQUET

- Black-Scholes model (=log-normal)
- volatility=0.2, risk-free=0.04
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- Pricing method: LS approximation
- **SMPC: only trade underlying stock**

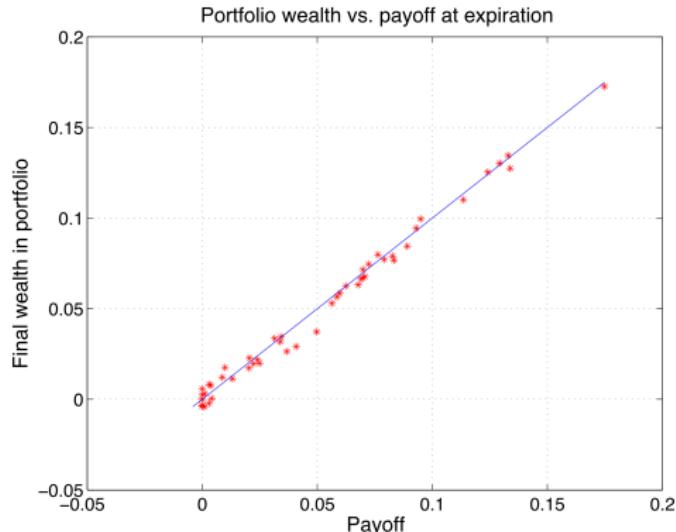

- ~~CPU time = 1400 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)~~

- CPU time = **50.5 ms** per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)
- CPU time = **76.7 s** to compute LS approximation (off-line)

Hedging quality is very similar !

EXAMPLE: BS MODEL, NAPOLEON CLIQUET

- Black-Scholes model (=log-normal)
- volatility=0.2, risk-free=0.04
- $T=24$ weeks (hedging every week)
- 50 simulations
- $M=100$ scenarios
- Pricing method: LS approximation
- **SMPC: Trade underlying stock & European call with maturity $t+T$**

- ~~CPU time = 1625 ms per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)~~

- CPU time = **59.2 ms** per SMPC step
(Matlab R2009 on 1.86GHz Intel Core 2 Duo)
- CPU time = **76.7 s** to compute LS approximation (off-line)

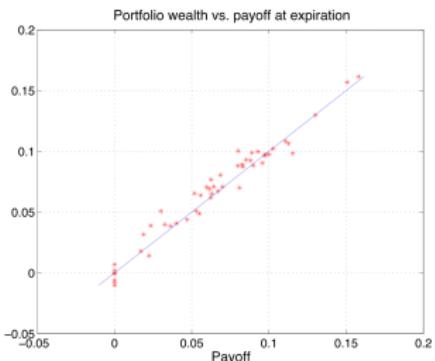

Hedging quality is very similar !

EXAMPLE: HESTON MODEL, NAPOLEON CLIQUET

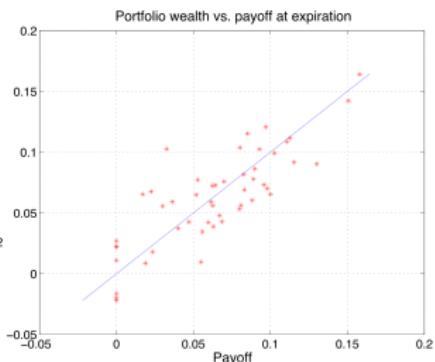

SMPC: only trade underlying stock

CPU time = 220 ms per SMPC step

SMPC: Trade underlying stock & European call with maturity $t+T$

CPU time = 277 ms per SMPC step

Delta hedging only trade underlying stock
CPU time = 156 ms per SMPC step

CPU time = 156 s to compute LS approximation (off-line)

SMPC FOR AUTOMOTIVE CONTROL

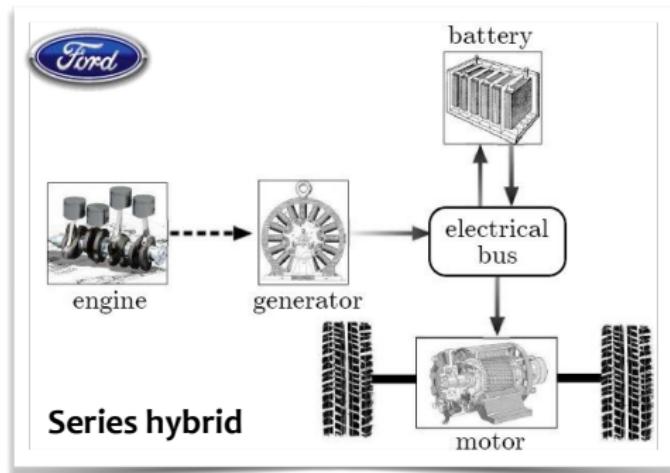

SMPC FOR HYBRID ELECTRIC VEHICLES (HEVs)

Control problem:

(Bichi, Ripaccioli, Di Cairano, Bernardini, Bemporad, Kolmanovsky, CDC 2010)

Decide optimal generation of **mechanical power** (from engine) and **electrical power** (from battery) to satisfy **driver's power request**

What will the future power request from the driver be ?

$$P_{req}(w(t)) = \text{driver's power request}$$

$$P_{req}(k) = P_{el}(k) + P_{mec}(k) - P_{br}(k)$$

LEARNING A STOCHASTIC MODEL OF THE DRIVER

- The driver action on the vehicle is modeled by the **stochastic** process $w(k)$
- Assume that the realization $w(k)$ can be **measured** at every time step k
- Depending on the **application**, $w(k)$ may represent different quantities (e.g., power request in an HEV, acceleration, velocity, steering wheel angle, ...)

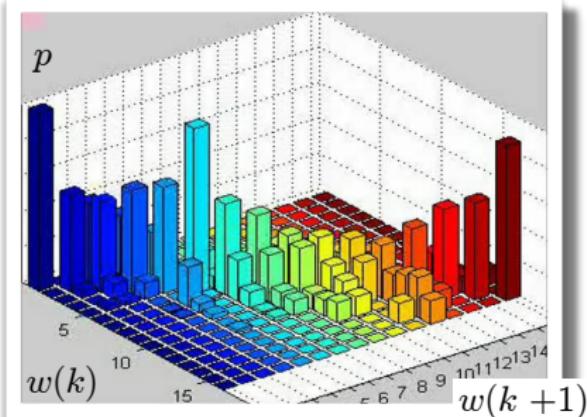

Good model for control purposes: $w(k) = \text{Markov chain}$

$$[T]_{ij} = \mathbf{P}[w(k+1) = w_j | w(k) = w_i]$$

Number of states in Markov chain determines the **trade-off** between complexity and accuracy

Transition probability matrix T is easily estimated from driver's data

Several model improvements are possible (e.g., multiple Markov chains)

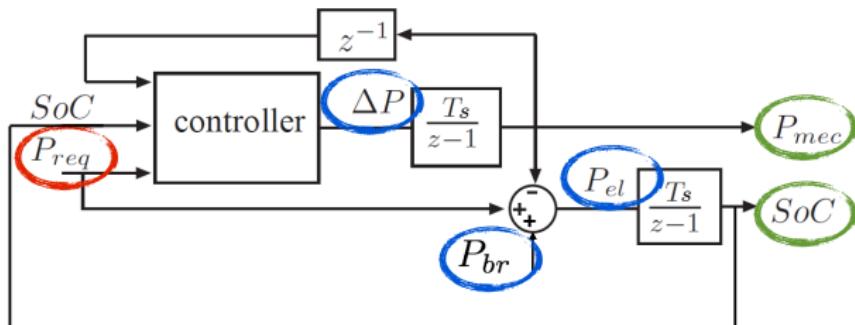

SMPC PROBLEM FOR HEV POWER MANAGEMENT

Manipulates inputs

$\Delta P(k)$, $P_{el}(k)$, $P_{br}(k)$

Uncertainty

$P_{req}(w(k))$

Controlled output

sample time $T_s = 1$ s

$$P_{req}(k) = P_{el}(k) + P_{mec}(k) - P_{br}(k)$$

Constraints

State-space equations

$$SoC(k+1) = SoC(k) - KT_s P_{el}(k)$$

$$P_{mec}(k+1) = P_{mec}(k) + \Delta P(k)$$

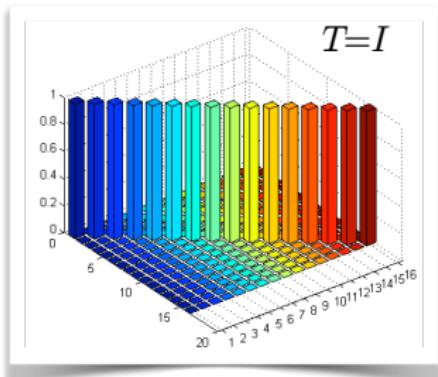

$$\begin{array}{lcl} SoC_{min} & \leq & SoC(k) & \leq & SoC_{max} \\ 0 & \leq & P_{mec}(k-1) & \leq & P_{mec,max} \\ P_{el,min} & \leq & P_{el}(k) & \leq & P_{el,max} \\ \Delta P_{min} & \leq & \Delta P & \leq & \Delta P_{max} \\ 0 & \leq & P_{br}(k) & & \end{array}$$

COMPARISON WITH DETERMINISTIC MPC

“Frozen-time” MPC (FTMPC)

No stochastic disturbance model,
simply ZOH along prediction horizon

$$P_{req}(w(t+k|k)) = P_{req}(w(k))$$

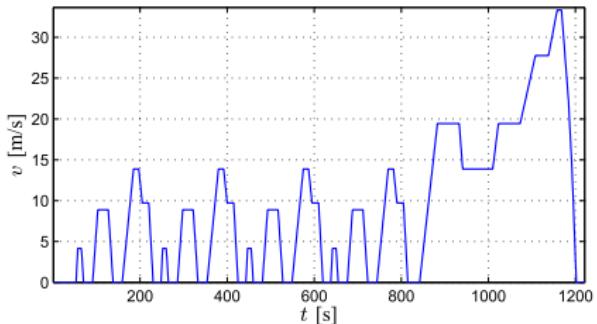

“Prescient” MPC (PMPC)

Future disturbance sequence $P_{req}(w(t+k|k))$
known in advance

STOCHASTIC MPC FOR ADAPTIVE CRUISE CONTROL

Problem setup

Goals

Control the follower acceleration variation (jerk) in order to:

- Improve safety (constraint on minimum distance)
- Improve comfort (reduce acceleration / deceleration)
- Track reference velocity

SMPG FOR ACC: PREDICTION MODEL

States

$a(k)$ acceleration

$v(k)$ velocity

$d(k)$ distance

$v_l(k)$ leader velocity

Dynamical Model

$$a(k+1) = a(k) + T_s u(k)$$

$$v(k+1) = v(k) + T_s a(k)$$

$$v_l(k+1) = v_l(k) + T_s a_l(k)$$

Inputs

$u(k)$ jerk

$a_l(k)$ leader
acceleration

Uncertainty

Stochastic leader acceleration

$$a_l(k) = w(k)$$

Constraints

$d(k) \geq d_{min}(k) = \delta + \gamma v(k)$ safety

$u_{min} \leq u \leq u_{max}$ comfort

References

$$d_{ref}(k) = \delta_{ref} + \gamma_{ref} v(k)$$

$$v_{ref} = 26 \text{m/s}$$

SMPc FOR ACC: STOCHASTIC LEADER MODEL

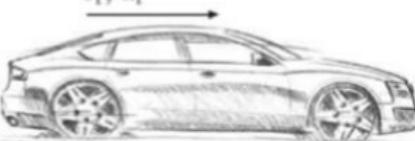

Follower vehicle
(equipped with ACC)

$$v, a \longrightarrow$$

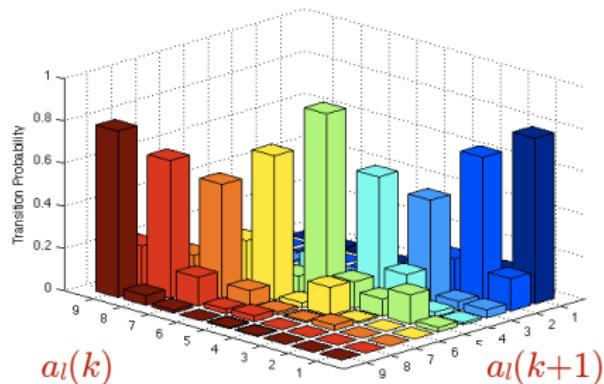

$$d$$

$$v_l, a_l \longrightarrow$$

Leader vehicle

Leader acceleration a_l modeled by a Markov Chain (quantized in **9 states**)

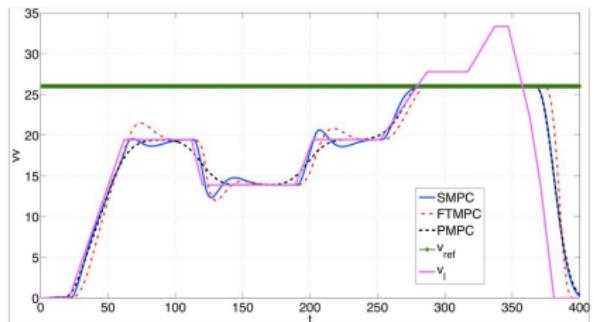

The Markov Chain is:

- Trained off-line on a collection of driving cycles (FTP, NEDC, 10-15 Mode)
- Adapted on-line by means of the learning algorithm

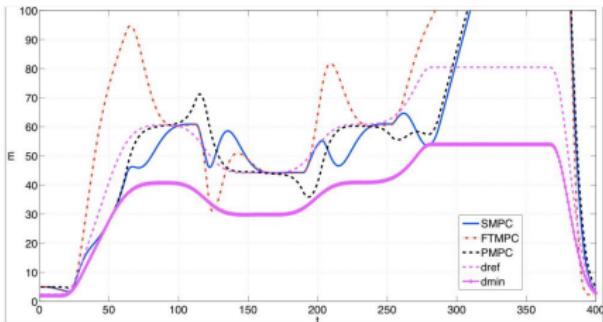

SMPC FOR ACC: SIMULATION RESULTS

Prescient MPC (black dashed line)

Simulation results on European Urban Driving Cycle (EUDC)

SMPC OF DRINKING WATER NETWORKS

DRINKING WATER NETWORK OF BARCELONA (SPAIN)

- General overview;

Municipalities supplied	23
Supply area	424 km ²
Population supplied	2.922.773
Average demand	7 m ³ /s

- Network parameters:

Pipes length	4.645 km
Pressure floors	113
Sectors	218
• Facilities	
Remote stations	98
Water storage tanks	81
Valves	64
Flow meters	92
Pumps / Pumping stations	180 / 84
Chlorine dosing devices	23
Chlorine analyzers	74

European FP7-ICT project WIDE "DEc~~e~~entralized and Wireless Control of Large-Scale Systems"

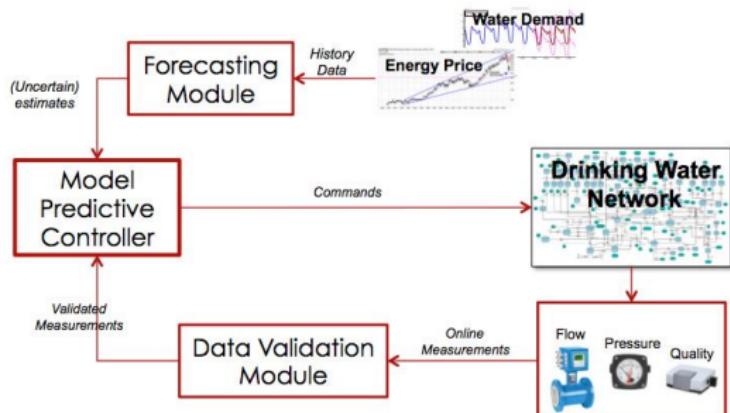

**European FP7-ICT project EFFINET
"EFFicient Integrated Real-time
Monitoring and Control of Drinking
Water NETworks"**

CONTROL OF THE DRINKING WATER NETWORK OF BCN

Main Goals:

- Reduce **electricity consumption** for pumping (€€€)
- Meet **demand** requirements
- Deliver **smooth** control actions
- Keep storage tanks above safety **limits**
- Respect the technical **limitations**: pressure limits, overflow limits & pumping capabilities

CONTROL OF THE DRINKING WATER NETWORK OF BCN

- The control objectives are translated into cost functions:

Expected total squared
water production cost
(ETSWPC) = **economic** cost

$$J^{ws} = W_\alpha^2 \sum_{l=1}^K \sum_{i=0}^{H_p-1} p^l (\alpha_1 + \alpha_{2,k})^2 (u_{k+i|k}^l)^2$$

Expected total smooth
operation cost (ETSOC)

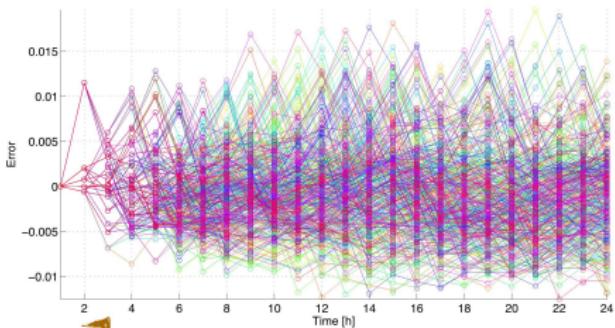

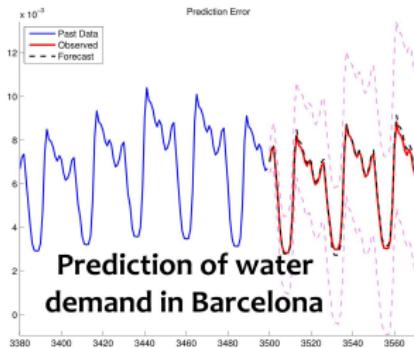

$$J^\Delta = \sum_{l=1}^K \sum_{i=1}^{H_p-1} p^l \ell^\Delta(\Delta u_{k+i|k}^l)$$

expected total **safety**
storage cost (ETSSC)

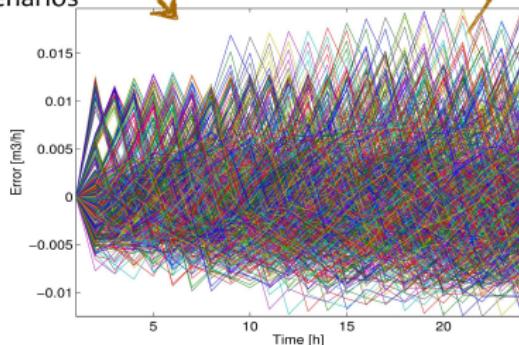

$$J^S = \sum_{l=1}^K \sum_{i=1}^{H_p} p^l \ell^s(x_{k+i|k}^l)$$

Need to minimize the total operating cost $V = J^{ws} + J^\Delta + J^S$

CONTROL OF THE DRINKING WATER NETWORK OF BCN

Uncertainty represented
as a fan of scenarios

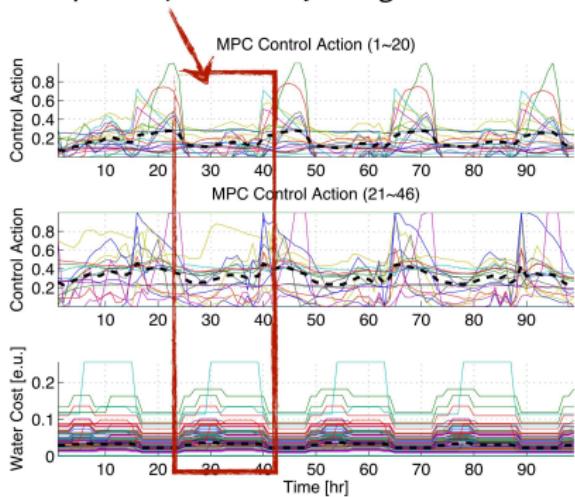

$$d_{k+i|k} = \hat{d}_{k+i|k} + \epsilon_{k+i|k}$$

Uncertainty:
demand prediction error

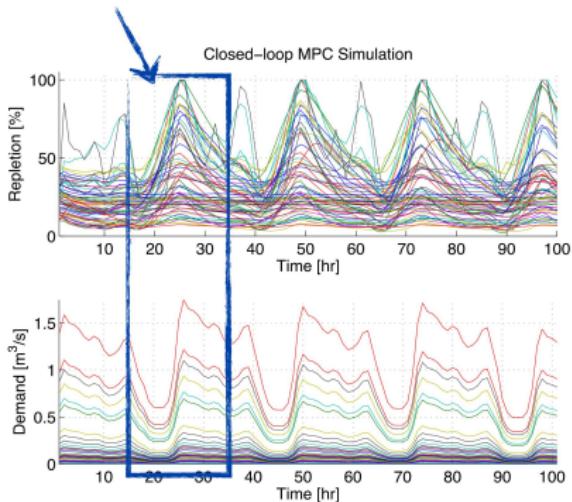

CONTROL OF THE DRINKING WATER NETWORK OF BCN

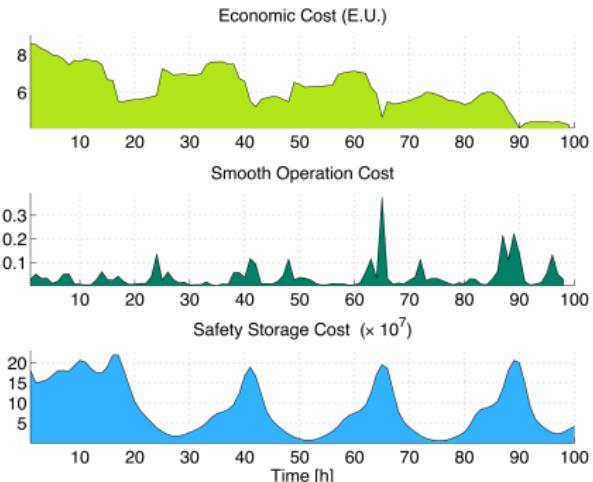

Economic: Avoid pumping when the price of electricity is high

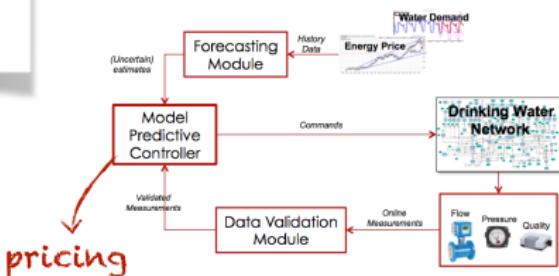

Foresight: tanks start loading up before the consumers ask for water

CONTROL OF THE DRINKING WATER NETWORK OF BCN

SMPC: The network operator has online information about the current and predicted operating cost in real time

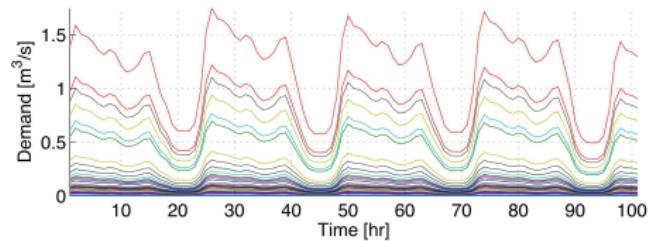

SCALABILITY OF THE SMPC APPROACH

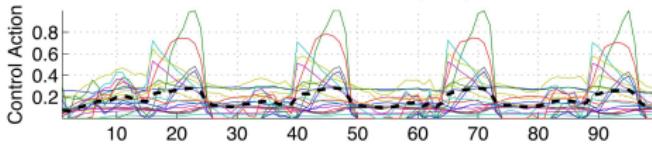

How does the approach **scale** with the dimension of the system ?

- The dGPAD algorithm scales-up well with the size of the scenario tree (thanks to heavy parallelization)
- Scalable alternatives:
 - **Decentralized SMPC**: divide into subsystems and control each of them in parallel, exchanging some decisions **after** computations (Bemporad, Barcelli, 2010)
(others' decisions = measured disturbances)
 - **Distributed SMPC**: exchange some global variables **during** computations (Negenborn, Maestre, IEEE CSM, 2014)
- The same dGPAD algorithm can be used for decentralized SMPC (immediately), or for distributed SMPC by relaxing also the constraints that (weakly) couple the subsystems

STOCHASTIC MPC AND PARALLEL COMPUTATIONS ON GPU

MPC Control Action (1~20)

MPC-controlled network:

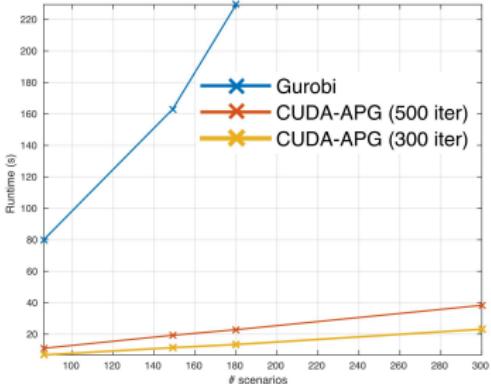

- Minimum pressure requirement hardly violated
- ~5% savings on energy cost w.r.t. current practice
- Smooth control actions
- sampling time = 1 hour

Drinking water network
of Barcelona:

63 tanks
114 controlled flows
17 mixing nodes

CPU time (s)

APG = Accelerated Proximal Gradient,
parallel implemented on NVIDIA Tesla
2075 CUDA platform

FP7-ICT project "EFFINET - Efficient Integrated Real-time Monitoring and Control of Drinking Water Networks" (2012-2015)
